sources of measurement error for manual tracings, and in general, DIA provides a technology that can at least partially overcome these problems. Finally, it is important to note that DIA provides information beyond the quantitative evaluation of traditional manual tracings. Because DIA involves digital photography, it provides an image and thus a basis for objective evaluation of other endpoints such as infection, lesion thickness, granulation status, surrounding edema, and lesion progression over time, if used at sequential time points. Overall, additional studies are needed to further assess the uses of DIA in quantitative evaluation of other cutaneous lesions and beyond.

Methods. We prospectively examined 15 patients with venous leg ulcers. The patients who underwent sequential imaging of chronic wounds for this study all attended the leg ulcer clinic of the Wound Healing Research Unit at the University of Pisa, Pisa, Italy.

Our sequential imaging system is equipped with a Vivid 900 laser scanner (Minolta, Osaka, Japan), which is used for digitizing or scanning the wound shape. With regard to the calculation of the "external" surface and volume of a wound, it is necessary to assess its original shape to determine the missing volume virtually. At the time of patient presentation, information on the shape of the skin before the wound occurred is missing, and the technique for virtual reconstruction of the original wound surface must be as easy and user-friendly as possible. The system, relying on an analysis of the shape of the surface immediately outside the wound perimeter, creates an interpolating virtual surface that is continuously connected to the existing surface outside the wound and to that covering it.

The parameters we studied were the mean wound area (measured in square centimeters) and mean volume (cubic centimeters). To assess interrater reproducibility, scans were evaluated by 2 independent investigators. For assessment of intrarater reproducibility, a single investigator performed 2 consecutive measurements 5 minutes apart. Immediately after the first wound assessment of the first observer, a second observer, blinded to the findings of the first analysis, measured the same wound.

The means and standard deviations of duplicate determinations for each wound were used for analysis. The reproducibility of measurements was evaluated by means of an intraclass correlation coefficient (ICC) and its 95% confidence interval (CI).

Results. The measured total areas and volumes for independent raters and for subsequent measures of 1 rater are...
The Diagnostic Yield of Histopathologic Sampling Techniques in PAN-Associated Cutaneous Ulcers

Polyarteritis nodosa (PAN), a medium-sized vessel (MSV) vasculitis, may result in cutaneous ulcers. There is no specific serologic abnormality associated with PAN; therefore, the mainstay diagnosis consists of histologic evidence of MSV vasculitis in the context of pertinent clinical findings. Several factors may contribute to the potential low diagnostic yield of tissue biopsy specimens from MSV-vasculitic ulcers. The present study evaluates the role of tissue sampling in the histologic evaluation of PAN-associated cutaneous ulcers.

Methods. Retrospective analysis of de-identified archival biopsy specimens taken from skin ulcers and sural nerves of 29 patients with histologically proven PAN-associated MSV vasculitis. Patients met the classifica-

Comment. The laser scanner system used in this study enables users to accurately acquire 3-dimensional digital models of various types of skin wounds. Since the final users will be physicians and not computer experts, a user-friendly system is believed to be a fundamental parameter for its success.

The accuracy of scanning systems has improved in the past few years, and prices have also decreased, making these devices affordable for a wider community of potential users. The integration into a single system of capabilities that can capture the shape and surface reflection characteristics makes 3-dimensional scanning an invaluable resource in all those applications where it is necessary to sample both surface attributes.
